Lupinus sulphureus Dougl. ssp. kincaidii (Smith) Hitchc.

Kincaid's sulfur lupine Fabaceae (Pea Family)

Status: State Endangered, USFWS Proposed Threatened

Rank: G5T2S1

General Description: Perennial with a branched crown, the usually numerous stems mostly simple, 16-32 inches tall, strigillose to somewhat whitish- or brownish-sericeous; basal leaves usually present and persistent until after flowering, the lowermost petioles 3-5 times as long as the blades, the upper cauline leaves with petioles sometimes shorter than the blades; leaflets 9-11, rather narrowly oblanceolate, usually acutish, 1 to 1½ inches long, glabrous above; racemes short-pedunculate, 4 to 7 inches long; flowers rather numerous but not closely crowded, scattered to imperfectly verticillate, 3/8 to 1/2 inch long, yellowish-cream colored, often with shades of blue on the keel; pedicels 1/8 to 3/8 inch long; calyx silky, often noticeably asymmetrical but not truly saccate or spurred, the upper lip bidentate, the lower entire: banner not much reflexed from the wings and keel, glabrous or very sparsely hairy on the back; wings glabrous; keel usually ciliate most of the length but sometimes glabrous: pods ³/₄ to 1 ¹/₈ inch long; seeds 4-5, pinkish-brown.

Identification Tips: With its low growing habit and unbranched inflorescence, *Lupinus sulphureus* ssp. *kincaidii* is easily distinguished from other members of the genus which occur in the same range.

Phenology: Flowers April through June.

Range: Regional endemic: Douglas County, OR north to Lewis County, WA.

Habitat: Native upland prairies as well as open oak woodlands. Soils are mesic to slightly xeric.

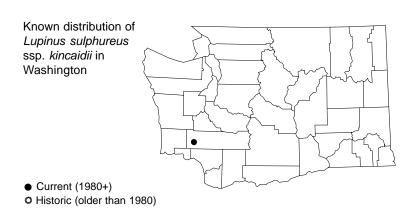

Ecology: The prairie habitat occupied by *Lupinus sulphureus* ssp. *kincaidii* was historically maintained by periodic disturbance; without disturbance, trees invade the prairies. *Lupinus sulphureus* ssp. *kincaidii* is the primary host plant of the endangered Fender's blue butterfly (*Icaricia icarioides fenderi*). Adult butterflies lay their eggs on the lupine "host" plants during May

Kincaid's sulphur lupine

Ecology (continued): and June. Newly hatched caterpillars feed and develop on the host plant until they transform into adult butterflies the following spring (USFWS 1998a).

State Status Comments: This species is a rare, regional endemic. It is currently only known from 2 locations in Washington less than a mile apart.

Inventory Needs: Suitable habitats throughout southwestern Washington need to be systematically inventoried for this taxon.

Threats and Management Concerns: Habitat loss due to agricultural activities, urban development, roadside maintenance, and herbicide application is the greatest threat to the taxon.
